Method for Training a Neural Network		Hirt, Joseph P.	2121	

**Comments on Statement of Reasons for Allowance**

Mail Stop ISSUE FEE  
Commissioner for Patents  
P.O. Box 1450  
Alexandria, VA 22313-1450

Sir:

In response to the examiner's Statement of Reasons for Allowance included with the Notice of Allowability mailed May 26, 2005, please consider the following comments:

**The Examiner's Statement of Reasons**

The following is the examiner's Statement of Reasons for Allowance:

The cited prior art taken alone or in combination fails to teach the claims invention of a method for training a neural network, to include pruning, to identify a patient risk function based on patient data and stipulated in the specification in paragraph 5.3 based on the survival function  $S(t)$  wherein the task of the neural network is to model the curve of the risk function  $\lambda(t)$  in the same way as a series expansion characterized by:

$$\lambda_0 \cdot \exp[\sum_0 B_0(t) \cdot A_0]$$

where :

$\lambda_0$  is a scaling factor,

Application No. 10/049,650  
Comments on Statement of Reasons for Allowance

Page 2

$A_0$  represents parameters that are the response signals of the neurons  $N_0$  of the output layer of the neural network, and

$B_0(t)$  represents a set of base functions of the series expansion that enable good approximation to the actual curve of the risk function.

The closest prior art (Mehrotra, Elements of Artificial Neural Networks, MIT Press, 1997) teaches training and pruning of neural networks. Mehrotra does not teach training a neural network to represent a series expansion wherein data representing such series expansion is formulated from patient data in an exponential summation format to include pruning represented by the singular act of neuron removal.

Comments

The allowed independent claims are claims 12 and 24. Allowed claim 12 reads as follows:

12. A method for training a neural network in order to identify a patient risk function such that the structure of the neural network is simplified, wherein the neural network includes

- an input layer having a plurality of input neurons that receive input data,
- at least one intermediate layer having a plurality of intermediate neurons,
- an output layer having a plurality of output neurons that provide output signals, wherein the output signals define the patient risk function following a first occurrence of a disease on the basis of given training data records including objectifiable and metrologically captured data relating to the medical condition of a patient, and

Page 3

- a multiplicity of synapses, wherein each said synapse interconnects a first neuron of a first layer with a second neuron of a second layer, defining a data sending and processing direction from the input layer toward the output layer, wherein the method comprises:

identifying and eliminating synapses of the multiplicity of synapses that have an influence on the curve of the risk function that is less than a predetermined significance, including

determining pre-change output signals of the neural network,  
selecting first and second sending neurons that are connected to the same receiving neuron by respective first and second synapses,  
assuming a correlation of response signals from said first and second sending neurons to the same receiving neuron,  
interrupting the first synapse and adapting in its place the weight of the second synapse,  
determining post-change output signals of the neural network,  
comparing the post-change output signals with the pre-change output signals,  
and  
eliminating the first synapse if the comparison result does not exceed a predetermined level.

Thus, claim 12 does not recite training a neural network to represent a series expansion wherein data representing such series expansion is formulated from patient data in an exponential summation format to include pruning represented by the singular

Application No. 10/049,650

Page 4

act of neuron removal. Specifically, claim 12 does not recite a patient risk function based on patient data based on the survival function  $S(t)$  wherein the task of the neural network is to model the curve of the risk function  $\lambda(t)$  in the same way as a series expansion characterized by  $\lambda_0 \cdot \exp[\sum_0 B_0(t) \cdot A_0]$ . Limitations of this type are not recited or suggested in claim 12 or in the dependent claims. Further, limitations of this type were not discussed in any of the examiner's actions, nor in any of the responses thereto, nor in any of the telephone interviews conducted between the undersigned and the examiner. It is respectfully submitted that no limitations of this type should be imputed to the claims based on the examiner's statement of reasons for allowance, and the claims should be given the broadest interpretation based on the literal meaning of the claims in view of the prosecution history prior to allowance.

Allowed claim 24 reads as follows:

24. A method for training a neural network in order to identify a patient risk function such that the structure of the neural network is simplified, wherein the neural network includes

- an input layer having a plurality of input neurons that receive input data,
- at least one intermediate layer having a plurality of intermediate neurons,
- an output layer having a plurality of output neurons that provide output signals, wherein the output signals define the patient risk function following a first occurrence of a disease on the basis of given training data records including objectifiable and metrologically captured data relating to the medical condition of a patient, and

Page 5

- a multiplicity of synapses, wherein each said synapse interconnects a first neuron of a first layer with a second neuron of a second layer, defining a data sending and processing direction from the input layer toward the output layer, wherein the method comprises:

identifying and eliminating synapses of the multiplicity of synapses that have an influence on the curve of the risk function that is less than a predetermined significance, including

determining pre-change output signals of the neural network,  
selecting a synapse,  
assuming that the selected synapse does not have a significant influence on the curve of the risk function,  
interrupting the selected synapse,  
determining post-change output signals of the neural network,  
comparing the post-change output signals with the pre-change output signals,  
and  
eliminating the selected synapse if the comparison result does not exceed a predetermined level.

Thus, claim 24 does not recite training a neural network to represent a series expansion wherein data representing such series expansion is formulated from patient data in an exponential summation format to include pruning represented by the singular act of neuron removal. Specifically, claim 24 does not recite a patient risk function based on patient data based on the survival function  $S(t)$  wherein the task of the neural network

is to model the curve of the risk function  $\lambda(t)$  in the same way as a series expansion characterized by  $\lambda_0 \cdot \exp[\sum_0 B_0(t) \cdot A_0]$ . Limitations of this type are not recited or suggested in claim 24 or in the dependent claims. Further, limitations of this type were not discussed in any of the examiner's actions, nor in any of the responses thereto, nor in any of the telephone interviews conducted between the undersigned and the examiner. It is respectfully submitted that no limitations of this type should be imputed to the claims based on the examiner's statement of reasons for allowance, and the claims should be given the broadest interpretation based on the literal meaning of the claims in view of the prosecution history prior to allowance.
